Experiment 13 — Case Study on Low-Code Limitations

Aim

To study the limitations of low-code development through a case study of a loan application management system.

Theory

Low-code development allows applications to be created using visual development tools, predefined components and limited amounts of code. Although it speeds up development, it has certain limitations.

Case study: Loan Application & Pre-Screening Management

A financial organization wants to manage loan applications, applicant details, branch information and application status using Zoho Creator.

Advantages of low-code development

1. Faster application development.
2. Reduced amount of manual coding.
3. Easier creation of forms and reports.
4. Built-in workflow automation.
5. Easier maintenance for simple business applications.

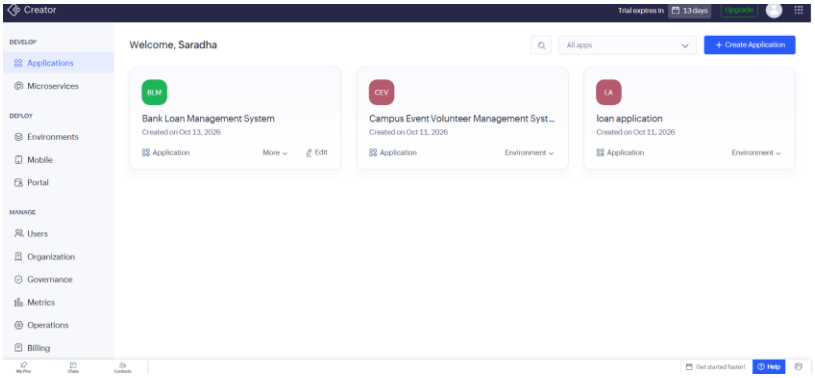

Limitations

1. Platform dependency: Applications depend on the platform's capabilities and policies.
2. Customization limits: Highly specialized functionality may require external code or services.
3. Integration challenges: Connecting external systems may require APIs and authentication.
4. Performance constraints: Complex operations and large datasets may need careful optimization.
5. Vendor lock-in: Moving to another platform may require redesign or migration.

6. Licensing limitations: Some features may require a paid plan.
7. Security responsibility: Permissions and sensitive data still need proper management.

Possible solutions

- Use efficient workflows and scripts.
- Integrate external services when necessary.
- Review platform limits and licensing.
- Apply security and testing practices.
- Use pro-code extensions for specialized requirements.

Result

The advantages and limitations of low-code development were studied using the loan application management system as a case study.
